

MIRCE Science

According to Knezevic [1] the purpose of existence of any functionable system¹ is to do functionability work, which is considered to be done when the expected measurable function is performed through time. However, experience teaches us that in-service life of functionable systems is frequently beset by undesirable negative functionability events, resulting from a variety of negative functionability actions (overstress, wearout, natural events, and human interventions). For the work to be continued, positive functionability actions, (servicing, repairing, testing, replacing, changing the mode of operation and similar) must be performed on the system. Thus, the complex interactions between positive and negative functionability actions govern the functionability performance of functionable systems, primarily measured through work done and resources consumed expressed through monetary values (functionability cost). Regrettably the functionability performance becomes known only at the end of the life of functionable system², when nothing could be done to influence it. Hence, the ability to accurately and quantitatively predict functionability performance of the future functionable systems at the design stages, when all possible changes could be done, would be invaluable for all project: engineers, planners, managers and strategist. The mixture of engineering solutions and management methods chosen to govern occurrences of functionability events, uniquely impact the expected functionability work, the expected cost and the expected return on the investment (e.g. profit, public benefit, reputation and similar).

Decades of research have generated a theoretical body of knowledge, named MIRCE Science, that comprises of axioms, system of formulas and methods that enable predictions of functionability performance of the future functionable system to be done, based on the complex interactions between: physical properties of consisting components, operational rules, maintenance policies, support strategies and expected environmental conditions. [1]

MIRCE Science is based on the scientific understanding of the mechanisms that generates the occurrences of functionability events, considered within a physical scale between 10^{-10} m (atomic scale) and 10^{10} m (solar system scale). [1] These mechanisms, together with the applied human rules, shape the expected pattern of the motion of a functionable system through MIRCE Space³. The “normalised” life-long pattern expected to be generated by each feasible type of functionable system is predictable, from the early stages of the design, by making use of the MIRCE Functionability Equation, which is the bedrock for calculation of the expected functionability performance.

¹ Functionable system is a set of physical entities and human rules that are put together to deliver at least one measurable function [1]

² Pan Am's Boeing 747, registration number N747PA, during the 22 years of in-service life, has delivered 80,000 hours of positive work (transported 4,000,000 passengers, burned 271,000,000 gallons of fuel) while receiving 806,000 man-hours of maintenance work (consuming: 2,100 tyres, 350 brake systems, 125 engines, among other parts).

³ MIRCE Space: a conceptual 3-dimensional space containing MIRCE Functionability Field, which is an infinite but countable set of all possible functionability states that a functionable system could be found in, and the probability of being in that state at each instance of calendar time. [1]
